

Lecture - 8 - OSI Model In Depth

* MAC Address

- Media Access Control Address.
- It is unique, so it doesn't change.
- Also known as Physical Address.

* NIC [Network Interface Card]

↓
Jitne Ways se Internet connect kar sakta → NIC

No. of MAC Address = No. of ways to connect with Internet.

- Only devices had only one way of connecting to Internet, so only one MAC address was there.
- MAC Address doesn't change and is not provided by Internet, but when way of connecting to Internet changes, MAC address changes, it is assigned to you only.

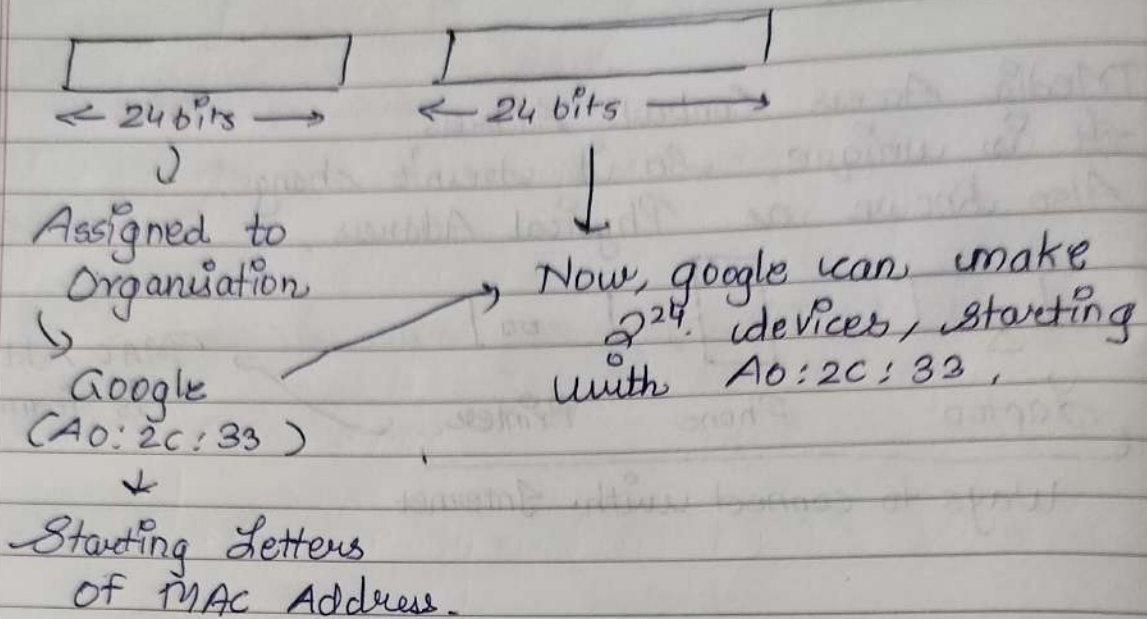

* Format of MAC Address.

- 48 bit number, represented in Hexa-decimal form.

[00:00:00:00:00:00]
[FF:FF:FF:FF:FF:FF]

↓ ↓
4 bit 4 bit ⇒ 6 * 8 = 48 bits
Portion 4+4=8

* How MAC is distributed.

Eg → Orade

(34:28:6F)

They can also make 2^{24} devices.

- MAC Address is 12 digit hexadecimal number, basically 48 digit binary number.

* Notation of MAC Address

1) Hyphen Hexadecimal notation]

00-0a-83-b1-c0-8e

2) Colon - Hexadecimal notation]

00:0a:83:b1:c0:8e

3) Period separated hexadecimal notation]

000.a83.b1c.00

* Data Link Layer.

- 1) Hop to Hop delivery
- 2) Giving Physical Address.

- I can transfer/send data using MAC address in that particular network.
- Router will assign Private IP Address & those private IP address are known by devices.
- ARP → Address Resolution Protocol.

- You want to send data but don't know MAC address of that 'B' device. 'A' will broadcast message with help of IP & **ARP** will request broadcast to all device (give MAC of B) and 'B' will respond with MAC Address.
- ARP helps to find MAC Addresses of devices in the particular network.

* Broadcasting

- Jab bhi IP Address Allocate hote.

\swarrow \searrow
 23.0.0.0 23.255.255.255
 (n/w address) (broadcast address)

- For Hop-to-Hop delivery we need MAC Address.

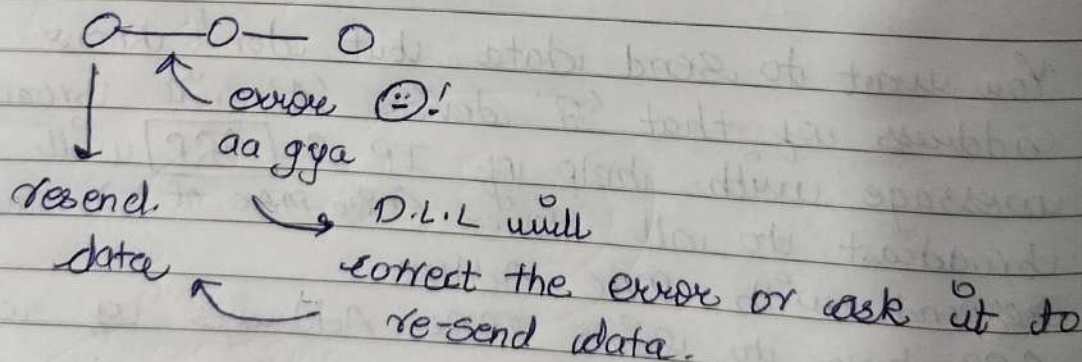

- You did Cyber Crime 😊

↳ Your ISP will know which website you visit (IP)

↓
But how ISP will know, device will allocate to that IP.

Use of MAC Address, → Now, ISP will search for MAC Address.
↓
Now, You are Caught 😞!

* Error Detection & Correction.

* Framing

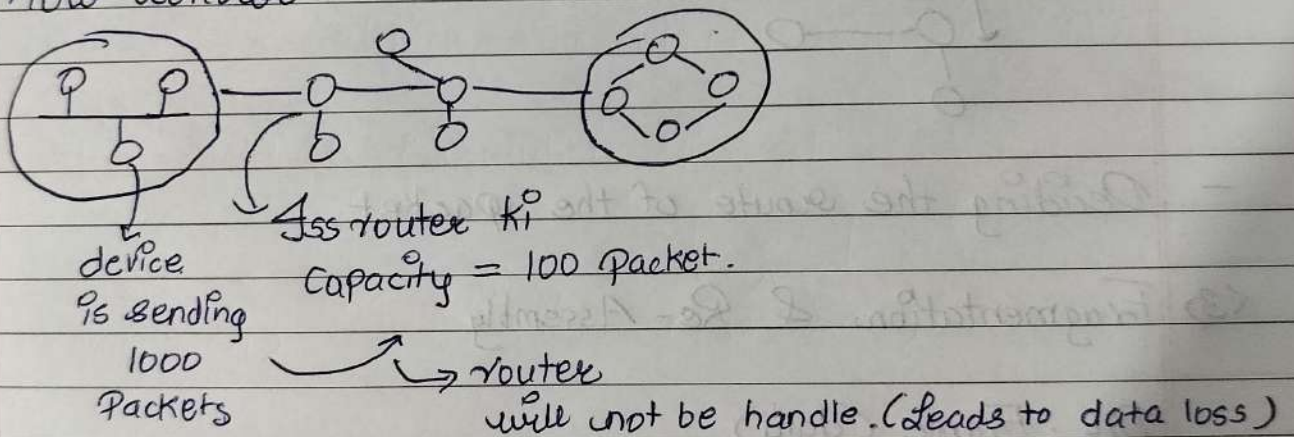

- There should be some pattern, so that B understands that data, is about to come.

- D.L.L sends data as 101010...11 to B, so that B gets ready to receive data.

- As soon as B will read 11, it will become ready to read original data.

* Flow Control

- Same packets ko EK bath nahi Bhejna.
- Sending desired amount of data to devices in sequence is called flow control.

* Access Control

- Pehle D wala C ko send Karega then B wala A ko.
- This controlling of devices is done by D.L.L and it is called Accessing. This improves efficiency of cables.

[3] Network Layer

(1) Assigning Logical Address

↓
Device ko IP Address dena.

- Logical Address = IP Address

- Connecting Sender & Receiver.

(2) Routing

- Router has 3 Layers.

- Deciding the route of the packet.

(3) Fragmentation & Re-Assembly

DLL : Frame (data)

NL : Packet (data)

This packet will be divided in fragments.

After reaching dest, they are re-assembled.

<4> Congestion Control

A lot of
data is being
sent

Traffic
is created

Delay, Collision
& data loss

- If all senders will send data, then traffic will be created.
- There should be a systematic way (protocols) through which data should be sent.
- Bandwidth is max. speed through which data can transmit over a network.
- Throughput is actual speed through which data is being transferred.
